

1. The first step is to identify the variables that are being measured. In this case, the variables are the number of hours worked per week and the number of hours spent on household chores per week.

2. The second step is to determine the units of measurement for each variable. The units for the number of hours worked per week are hours per week, and the units for the number of hours spent on household chores per week are hours per week.

3. The third step is to collect data for each variable. This can be done by asking respondents to report the number of hours they work per week and the number of hours they spend on household chores per week.

4. The fourth step is to analyze the data. This can be done by calculating the mean, median, and standard deviation for each variable, and by comparing the two variables.

5. The fifth step is to draw conclusions from the data. This can be done by interpreting the results of the analysis and making statements about the relationship between the two variables.
